Abstract. We introduce a new type of generalized Turing machines (GTMs), which are intended as a tool for the mathematician who studies computability in Analysis. In a single tape cell a GTM can store a symbol, a real number, a continuous real function or a probability measure, for example. The model is based on TTE, the representation approach for computable analysis. As a main result we prove that the functions that are computable via given representations are closed under GTM programming. This generalizes the well known fact that these functions are closed under composition. The theorem allows to speak about objects themselves instead of names in algorithms and proofs. By using GTMs for specifying algorithms, many proofs become more rigorous and also simpler and more transparent since the GTM model is very simple and allows to apply well-known techniques from Turing machine theory. We also show how finite or infinite sequences as names can be replaced by sets (generalized representations) on which computability is already defined via representations. This allows further simplification of proofs. All of this is done for multi-functions, which are essential in Computable Analysis, and multi-representations, which often allow more elegant formulations. As a byproduct we show that the computable functions on finite and infinite sequences of symbols are closed under programming with GTMs. We conclude with examples of application.

1. Introduction

In 1955 A. Grzegorczyk and D. Lacombe [12, 13, 16] proposed a new definition of computable real functions. Their idea became the basis of a general approach to computability in Analysis, TTE (Type-2 Theory of Effectivity), also called the "representation approach to computable analysis" [15, 20, 18, 9]. TTE supplies a uniform method for defining natural computability on a variety of spaces considered in Analysis such as Euclidean space, spaces of continuous real functions, open, closed or compact subsets of Euclidean space, computable metric spaces, spaces of integrable functions, spaces of probability measures, Sobolev spaces and spaces of distributions. There are various other approaches for studying computability in Analysis [20, Chapter 9], but for this purpose, still TTE seems to be the most useful one.

1998 ACM Subject Classification: F.1.1, F.1.m.
Key words and phrases: computable analysis, model of computation, generalized Turing machine.

In TTE computability of functions on Σ^*, the set of finite words, and Σ^ω, the set of infinite sequences over a finite alphabet Σ, is defined explicitly by, for example, "Type-2 Turing machines". Via notations $\nu : \Sigma^* \to X$ or representations $\delta : \Sigma^\omega \to X$, such "concrete" finite or infinite sequences are used as "names" for "abstract" objects such as real numbers, continuous real functions etc. A function on the abstract objects is called computable, if it can be realized by a computable function on names.

In ordinary computability theory, for proving computability of a word function $g : (\Sigma^*)^n \to \Sigma^*$, in general it is not necessary to write a (usually very long) code of a Turing machine. Instead it suffices to sketch an algorithm that uses some "simpler" functions already known to be computable. The method can be formalized by introducing an abstract model of computation, for example, Turing machines (let us call them "P-machines") that in addition to the usual statements can use some additional word functions $f : (\Sigma^*)^n \to \Sigma^*$ for assignments ("subroutines"). A straightforward proof shows that the computable functions are closed (not only under composition but) under programming with P-machines. More precisely, the function f_M computed by a P-machine M that uses only computable functions as subroutines is computable, that is, computable by an ordinary Turing machine. Therefore, for proving computability of a function g it suffices to describe informally a P-machine M that uses only computable functions f as subroutines and to prove that $f_M = g$.

In TTE, the situation is similar. For proving computability of a function on "abstract" sets it must be shown that there is a realization that is computable on a Type-2 Turing machine. Since usually defining or even sketching a concrete Type-2 machine is much too cumbersome, in many articles only algorithms are sketched that use functions on "abstract" sets already known to be computable. For a while this method has been applied although its soundness has not been proved. In [21] the second author has closed this gap by introducing an abstract model of computation for TTE, namely flowcharts with indirect addressing and computable functions on abstract data as subroutines. However, for this model the technical framework of definitions, theorems and proofs has turned out to be complicated and nontransparent such that people preferred to continue with informal arguments rather than applying or mentioning the main results from [21].

In this article we introduce a very simple model of computation for computable analysis, called here generalized Turing machines. It generalizes the ordinary multi-tape Turing machines with finitely many tapes numbered from 0 to L, finitely many input tapes and one output tape as follows: a generalized Turing machine has a finite tape alphabet Γ and for each tape i a set X_i. Each cell of Tape i contains an element $x \in \Gamma \cup X_i$. In addition to the usual Turing machine statements on each tape (move left, move right, write $a \in \Gamma$, branch if $a \in \Gamma$ is scanned by the head) two further kinds of statements are allowed (where x_j is the content of the cell scanned by the head on Tape i):

(1) assignments "$i := f(i_1, \ldots, i_n)$ " where $f : X_{i_1} \times \ldots \times X_{i_n} \rightrightarrows X_i$ is a multi-function (meaning: write some $x \in f(x_{i_1}, \ldots x_{i_n})$ on the cell scanned by the head of Tape i),

(2) branchings "(if $f(i_1, \ldots, i_n)$ then l', else l'')" where $f :\subseteq X_{i_1} \times \ldots \times X_{i_n} \to \Sigma^*$ is a partial function (meaning: if $f(x_{i_1}, \ldots x_{i_n}) = 0$ then go to Label l', if $f(x_{i_1}, \ldots x_{i_n}) = 1$ then go to Label l'', and loop otherwise). (Σ will be an alphabet with $0, 1 \in \Sigma$.)

The model allows to use the universal computational power of Turing machines and for each set X_j used in a machine the number of elements $x \in X_j$ that can be stored during a computation is not bounded. Generalized Turing machines share these properties with the flowcharts with indirect addressing [21] and with the WhileCC* programs [19]. Our

generalized Turing machines can be considered also as a generalization of the BSS-machine [4, 3, 2]. In the BSS-model for the real numbers the algebraic operations and the test "$x < y$" are allowed. But in Computable Analysis the test "$x < y$" is and should not be computable [20, Chapter 9][6, 10].

In Section 2 we summarize some mathematical preliminaries, in particular realization of multi-functions by multi-functions via generalized multi-representations. Generalized multi-representations allow simpler but still abstract data as names instead of sequences of symbols. This generalizes [1] where domains are allowed as sets of names.

The new model of generalized Turing machines and their semantics are defined in Section 3. In Section 4 we generalize the concept of multi-representation from sets to machines and prove that realization is not only closed under composition but under programming with generalized Turing machines. In Section 5 we prove that for a generalized Turing machine M such that $Y_i \in \{\Sigma^*, \Sigma^\omega\}$ for all i that contains only computable functions on Σ^* and Σ^ω, the function f_M on Σ^* and Σ^ω is computable (accordingly for continuity) (Theorem 5.7 and Corollary 5.8 cf. [21, Theorem 15]).

The main results are proved in Section 6. If P is a generalized Turing machine where for every tape i the set Z_i is equipped with a multi-representation $\delta_i : \Sigma^\omega \rightrightarrows Z_i$ and every function on the Z_i used in the machine is relatively computable via the corresponding multi-representations, then the function f_P computed by the machine is relatively computable via the corresponding multi-representations (Theorem 6.2, cf. [21, Theorem 30]). Roughly speaking, the relatively computable functions are closed under programming. The theorem holds accordingly for continuous instead of computable functions. The theorem holds accordingly if the $\delta_i : Y_i \rightrightarrows Z_i$ are generalized multi-representations and the functions on the realizing sets Y_i used in the machine are computable w.r.t. a family $(\gamma_i : \Sigma^\omega \rightrightarrows Y_i)_i$ of multi-representations (Theorem 6.6, cf. [21, Theorem 31]). This theorem allows to use the concept of realization rigorously in a more abstract and often simpler way. Both theorems allow to formulate and argue about algorithms in terms of ordinary analysis and almost no mentioning of concrete representations. In Section 7 some examples illustrate the main results. In particular, we present a method for proving the relation $\leq_W$ introduced in [7] for comparing the non-computability theorems in analysis. As an addendum to this introduction the reader is referred to [21, Section 1].

2. Preliminaries

In this section we summarize some mathematical preliminaries. For more details see [20, 21]. Let Σ be a non-empty finite set which is called *alpahabet*. We assume $0, 1 \in \Sigma$. Classically, computability is introduced for functions $f :\subseteq (\Sigma^*)^n \to \Sigma^*$ on the set Σ^* of finite words over Σ, for example by means of Turing machines. For computing functions on other sets M such as natural numbers, rational numbers and finite graphs, words are used as codes or names of elements of M. Under this view a machine transforms words to words without understanding the meaning given to them by the user. We can extend this concept by using infinite sequences of symbols of Σ as names and by defining computability for functions which transform such infinite sequences. The set Σ^ω of infinite sequences of symbols from Σ has the same cardinality as the set of real numbers, therefore it can be used as a set of names for every set with at most continuum cardinality such as real numbers, the set of open subsets of $\mathbb{R}$ and the set $C[0, 1]$ of real continuous functions on the interval $[0, 1]$.

A *multi-function* from A to B is a triple $f = (A, B, R_f)$ such that $R_f \subseteq A \times B$ (the graph of f). We will denote it by $f : A \rightrightarrows B$. (The concept of multi-function can be considered as a generalization of the concept of partial function. There is no need for a separate notation for "total" multi-functions.) For $a \in A$, let $f(a) := \{b \in B | (a, b) \in R_f\}$. For $X \subseteq A$ let $f[X] := \{b \in B | (\exists a \in X)(a, b) \in R_f\}$, $\mathrm{dom}(f) := \{a \in A | f(a) \neq \emptyset\}$, and $\mathrm{range}(f) := f[A]$. If, for every $a \in A$, $f(a)$ contains at most one element, f is a usual partial function denoted by $f :\subseteq A \to B$. We write "$f(a)\downarrow$" ($f(a)$ exists) if $a \in \mathrm{dom}(f)$ and "$f(a)\uparrow$" ($f(a)$ diverges) if $a \notin \mathrm{dom}(f)$.

In the intended applications, for a multi-function $f : A \rightrightarrows B$, $f(a)$ is interpreted as the set of all results which are "acceptable" on input $a \in A$. Any concrete computation, a realization of f, will produce on input $a \in \mathrm{dom}(f)$ some element $b \in f(a)$, but often there is no method to select a specific one (see [17, 5, 20] and the examples in [21, Section 3]). The following definition of composition $g \circ f : A \rightrightarrows C$ of multi-functions $f : A \rightrightarrows B$ and $g : B \rightrightarrows C$ is in accordance with this interpretation: $a \in \mathrm{dom}(g \circ f)$ iff $(a \in \mathrm{dom}(f) \wedge f(a) \subseteq \mathrm{dom}(g))$ and $g \circ f(a) := g[f(a)]$ for all $a \in \mathrm{dom}(g \circ f)$. For the composition of multi-representations we will use the "relational" or "non-deterministic" composition $\odot$, see (6.1) in Section 6.

For $u, v \in \Sigma^* \cup \Sigma^\omega$, $u \sqsubseteq v$ (u is a *prefix* of v) iff $v = uw$ for some $w \in \Sigma^* \cup \Sigma^\omega$. For vectors over $\Sigma^* \cup \Sigma^\omega$ define $(u_1, \ldots, u_n) \sqsubseteq (v_1, \ldots, v_n)$ iff $(\forall i)\, u_i \sqsubseteq v_i$. Computable functions on Σ^* can be defined by Turing machines [14]. Computable functions on Σ^* and Σ^ω can be defined by Type-2 machines [20]. A *Type-2 machine* M is a multi-tape Turing machine with k input tapes (for some $k \geq 0$), finitely many work tapes and a single one-way output tape together with a type specification $(Y_1, \ldots, Y_k \to Y_0)$, $Y_i \in \{\Sigma^\omega, \Sigma^*\}$.

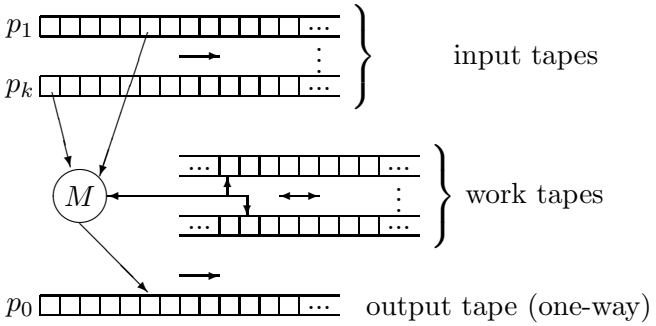

Figure 1: A Type-2 machine

The function $f_M :\subseteq Y_1 \times \cdots \times Y_k \to Y_0$ computed by the Type-2 machine M is defined as follows:
Case $Y_0 = \Sigma^*$: $f_M(p_1, \ldots, p_k) = w$, iff M halts on input $(p_1, \ldots, p_k)$ with $w \in \Sigma^*$ on the output tape;
Case $Y_0 = \Sigma^\omega$: $f_M(p_1, \ldots, p_k) = p_0$, iff M computes forever on input $(p_1, \ldots, p_k)$ and writes $p_0 \in \Sigma^\omega$ on the output tape.
We call a function $f :\subseteq Y_1 \times \cdots \times Y_k \to Y_0$ Turing computable, iff $f = f_M$ for some Type-2 machine M, and deviant from the usual terminology we call it computable, if it has a Turing computable extension. (Notice that usually "computable" means Turing computable.) The computable functions are closed under composition.

On Σ^* we consider the discrete topology and on Σ^ω the Cantor topology defined by the basis $\{u\Sigma^\omega \mid u \in \Sigma^*\}$ of open sets. As a fundamental result, every computable function on Σ^* and Σ^ω is continuous.

A *representation* of a set M is a surjective function $\delta :\subseteq Y \to M$ where $Y = \Sigma^*$ or $Y = \Sigma^\omega$. (Often the word "representation" is reserved for the case $\delta :\subseteq \Sigma^\omega \to M$ and surjective functions $\nu :\subseteq \Sigma^* \to M$ are called "notations" [20].) We will use *multi-representations* $\delta : Y \rightrightarrows M$ where $M = \mathrm{range}(\delta)$ ($Y \in \{\Sigma^*, \Sigma^\omega\}$). Here, a name $w \in y$ may be a name of many $x \in M$. Finally we use *generalized multi-representations* $\lambda : U \rightrightarrows M$ such that $\mathrm{range}(\lambda) = M$ where an arbitrary set U is considered as the set of "names".

If for a generalized multi-representation $\delta : U \rightrightarrows X$, $x \in \delta(u)$ then we say "u realizes x (via δ)" or "u is a name of x". The *realization* of functions by functions is a central concept in TTE. We define the most general case: the realization of a multi-function by a multi-function via generalized multi-representations.

Definition 2.1 (realization)**.** [21] Let $f : X_1 \times \ldots \times X_n \rightrightarrows X_0$ and $g : Y_1 \times \ldots \times Y_n \rightrightarrows Y_0$ be multi-functions and let $\gamma_i : X_i \rightrightarrows Y_i$ $(0 \le i \le n)$ be generalized multi-representations. For $x = (x_1, \ldots, x_n) \in X_1 \times \ldots \times X_n$ let $\gamma(x) := \gamma_1(x_1) \times \ldots \times \gamma_n(x_n)$.

Then "f realizes g via $(\gamma_1, \ldots, \gamma_n, \gamma_0)$" or "$f$ is a $(\gamma_1, \ldots, \gamma_n, \gamma_0)$-realization of g", iff for all $x \in X_1 \times \ldots \times X_n$ and $y \in Y_1 \times \ldots \times Y_n$,

$$y \in \gamma(x) \cap \mathrm{dom}(g) \implies \big(f(x) \neq \emptyset \ \wedge \ (\forall x_0 \in f(x))\, g(y) \cap \gamma_0(x_0) \neq \emptyset \big)\,. \tag{2.1}$$

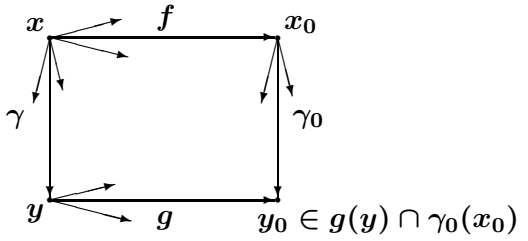

Figure 2: f realizes g via $(\gamma_1, \ldots, \gamma_n, \gamma_0)$.

Figure 2 illustrates the realization of g by f. Roughly speaking, provided x is a γ-name of $y \in \mathrm{dom}(g)$ then

	$f(x)$	is a name of	$g(y)$	if	f	is single-v. and	g	is single-v.,
	$f(x)$	is a name of some	$y_0 \in g(y)$	if	f	is single-v. and	g	is multi-v.,
every	$x_0 \in f(x)$	is a name of some	$y_0 \in g(y)$	if	f	is multi-v. and	g	is multi-v..

For further technical details see [20] and [21, Sections 1,2,3,6,8 (until Lemma 28) and 9].

3. Generalized Turing machines

We generalize multi-tape Turing machines [14] to generalized Turing machines as follows. A generalized Turing machine (GTM) has $L + 1$ tapes where Tapes $1, \ldots, k$ are the input tapes, Tapes $k + 1, \ldots, L$ are work tapes and Tape 0 is the output tape. There is a finite work alphabet Γ and the blank symbol $b \in \Gamma$. For an ordinary Turing machine, there is a finite input/output alphabet Σ such that $\Sigma \cap \Gamma = \emptyset$ and at any time every cell of every tape contains exactly one element ("symbol") $a \in \Sigma \cup \Gamma$. We generalize the definition by

assigning to every tape i a set X_i (which may be empty) such that at any time every cell of Tape i contains exactly one element $a \in X_i \cup \Gamma$.

As for an ordinary Turing machine every tape has a read/write head that scans exactly one cell and there is a finite set $\mathcal{L}$ of labels (usually called states) with an initial label $l_0 \in \mathcal{L}$ and a final label $l_f \in \mathcal{L}$. For every label $l \neq l_f$ there is a statement defining some action on some tape and the next label. As for an ordinary Turing machine in one step on some tape the head can be moved one position to the right or to the left, and for every symbol $a \in \Gamma$, a can be written on the cell scanned by the head and it can be tested whether a is scanned by the head (branching). Figure 3 shows the tapes and heads of a generalized Turing machine.

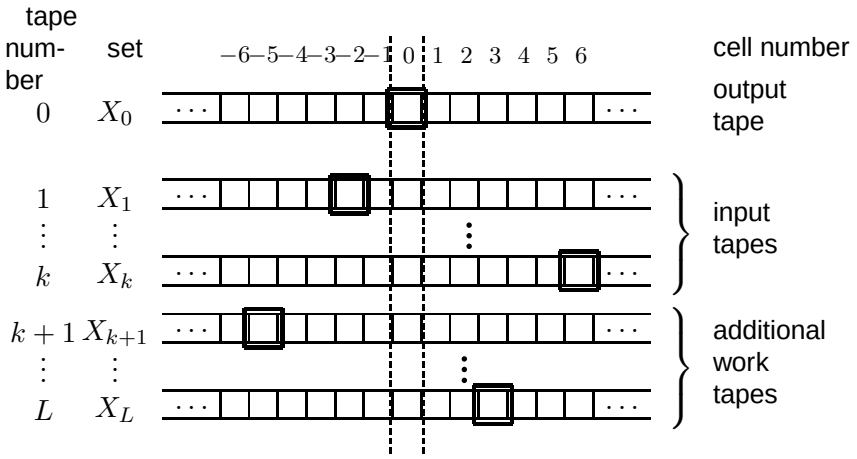

Figure 3: A generalized Turing machine.

Generalized Turing machines may have a further kind of assignments and a further kind of branchings. Let x_i be the content of the cell scanned by the head on Tape i ($0 \leq i \leq L$).

(1) "$(i := f(i_1, \ldots, i_n), l')$" for some $f : X_{i_1} \times \ldots \times X_{i_n} \rightrightarrows X_i$ meaning: write some $y \in f(x_{i_1}, \ldots x_{i_n})$ on the cell scanned by the head on Tape i and then go to Label l';

(2) "(if $f(i_1, \ldots, i_n)$ then l', else l'')" for some $f :\subseteq X_{i_1} \times \ldots \times X_{i_n} \to \Sigma^*$ meaning: if $f(x_{i_1}, \ldots x_{i_n}) = 0$ then go to Label l', if $f(x_{i_1}, \ldots x_{i_n}) = 1$ then go to Label l'' (and loop otherwise).

Definition 3.1. A generalized Turing machine (GTM) is a tuple $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0 \leq i \leq L}, \mathrm{Stm})$ such that:

(1) $\mathcal{L}$ is a finite set ("labels"), $l_0, l_f \in \mathcal{L}$ ("initial" and "final" label);
(2) Γ ("work alphabet") is a finite set, $\Sigma \cap \Gamma = \emptyset$ and $b \in \Gamma$ ("blank" symbol);
(3) $k, L \in \mathbb{N}$, $k \leq L$ ($0, 1, \ldots, L$: numbers of the tapes; $1, \ldots, k$: numbers of the input tapes; 0: number of the output tape);
(4) X_i is a set such that $X_i \cap \Gamma = \emptyset$ ($0 \leq i \leq L$);
(5) Stm is a function assigning to every label $l \in \mathcal{L} \setminus \{l_f\}$ a statement from the following list (where $\{i, i_1, \ldots, i_n\} \subseteq \{0, 1, \ldots, L\}$ and $l', l'' \in \mathcal{L}$):
   (a) (i, right, l'),
   (b) (i, left, l'),
   (c) $(i := a, l')$ (for some $a \in \Gamma$),

(d) $(i, \text{if } a \text{ then } l', \text{ else } l'')$ (for some $a \in \Gamma$),
(e) $(i := f(i_1, \ldots, i_n), l')$ (for some $f : X_{i_1} \times \ldots \times X_{i_n} \rightrightarrows X_i$);
(f) (if $f(i_1, \ldots, i_n)$ then l', else l'') (for some $f :\subseteq X_{i_1} \times \ldots \times X_{i_n} \to \Sigma^*$ with range$(f) \subseteq \{0, 1\}$).

Notice that for assignments (5e) we allow multi-valued functions while for tests (5f) the functions must be single-valued but may still be partial. For defining the semantics we formalize the tape i with inscription by a function $\alpha_i : \mathbb{Z} \to X_i \cup \Gamma$ and the head position by a number $m_i \in \mathbb{Z}$. In the branching (5f) we will interpret $0 \in \Sigma^*$ as true and $1 \in \Sigma^*$ as false.

Definition 3.2 (semantics)**.** Let $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0 \le i \le L}, \mathrm{Stm})$ be a generalized Turing machine.

(1) Let $\mathcal{S} := \prod_{i=0}^{L}((X_i \cup \Gamma)^{\mathbb{Z}} \times \mathbb{Z})$ be the set of *states* and $\mathcal{K} := \mathcal{L} \times \mathcal{S}$ be the set of *configurations*. For a configuration $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ define local modifications of κ as follows:
$\kappa[\text{label} \leftarrow l_1]$: in κ replace the label by l_1
$\kappa[\text{head}_i \leftarrow m]$: in κ move the head on Tape i to Position m,
$\kappa[\text{cell}_i \leftarrow x]$: in κ write x under the head of Tape i .
(2) We define a successor relation $\vdash \subseteq \mathcal{K} \times \mathcal{K}$. Let $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ and $x_j := \alpha_j(m_j)$ for $0 \le j \le L$. The successors of κ are determined by the statement $\mathrm{Stm}(l)$ as follows: $\kappa \vdash \kappa'$ iff:
(a) $\mathbf{Stm(}\boldsymbol{l}\mathbf{) = (}\boldsymbol{i}\mathbf{, right, }\boldsymbol{l'}\mathbf{)}$: $\kappa' = \kappa[\text{head}_i \leftarrow m_i + 1]\,[\text{label} \leftarrow l']$,
(b) $\mathbf{Stm(}\boldsymbol{l}\mathbf{) = (}\boldsymbol{i}\mathbf{, left, }\boldsymbol{l'}\mathbf{)}$: $\kappa' = \kappa[\text{head}_i \leftarrow m_i - 1]\,[\text{label} \leftarrow l']$,
(c) $\mathbf{Stm(}\boldsymbol{l}\mathbf{) = (}\boldsymbol{i} \mathbf{:=} \boldsymbol{a}\mathbf{, }\boldsymbol{l'}\mathbf{)}$: $\kappa' = \kappa[\text{cell}_i \leftarrow a]\,[\text{label} \leftarrow l']$,
(d) $\mathbf{Stm(}\boldsymbol{l}\mathbf{) = (}\boldsymbol{i}\mathbf{, if }\boldsymbol{a}\mathbf{ then }\boldsymbol{l'}\mathbf{, else }\boldsymbol{l''}\mathbf{)}$:
$\kappa' = \kappa[\text{label} \leftarrow l']$ if $x_i = a$, and $\kappa' = \kappa[\text{label} \leftarrow l'']$ if $x_i \neq a$,
(e) $\mathbf{Stm(}\boldsymbol{l}\mathbf{) = (}\boldsymbol{i} \mathbf{:=} \boldsymbol{f}\mathbf{(}\boldsymbol{i_1}\mathbf{, \ldots, }\boldsymbol{i_n}\mathbf{)}\boldsymbol{,}\ \boldsymbol{l'}\mathbf{)}$:
$\kappa' = \kappa[\text{cell}_i \leftarrow x]\,[\text{label} \leftarrow l']$ for some $x \in f(x_{i_1}, \ldots, x_{i_n})$,
(f) $\mathbf{Stm(}\boldsymbol{l}\mathbf{) = (if }\boldsymbol{f}\mathbf{(}\boldsymbol{i_1}\mathbf{, \ldots, }\boldsymbol{i_n}\mathbf{)\ then }\boldsymbol{l'}\mathbf{, else }\boldsymbol{l''}\mathbf{)}$:
$\kappa' = \kappa[\text{label} \leftarrow l']$ if $f(x_{i_1}, \ldots, x_{i_n}) = 0$, and
$\kappa' = \kappa[\text{label} \leftarrow l'']$ if $f(x_{i_1}, \ldots, x_{i_n}) = 1$.
(3) A *computation* is a (finite or infinite) sequence $(\kappa^0, \kappa^1, \ldots)$ of configurations such that $\kappa^i \vdash \kappa^{i+1}$. A computation is *maximal* if it is infinite or its last configuration has no $\vdash$-successor. A configuration $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ is *accepting* if $l = l_f$ and $\alpha_0(0) \in X_0$. An *accepting computation* is a finite computation $(\kappa_0, \kappa_1, \ldots, \kappa_n)$ such that κ_n is accepting.
(4) For $(x_1, \ldots, x_k) \in X_1 \times \ldots \times X_k$ define the initial configuration by

$$\mathrm{IC}(x_1, \ldots, x_k) := (l^0, (\alpha_0^0, 0), \ldots, (\alpha_L^0, 0))$$

where $l^0 = l_0$, $\alpha_i^0(0) = x_i$ for $1 \le i \le k$ and $\alpha_i^0(j) = b$ for all other (i, j). For every configuration $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ define

$$\mathrm{OC}(\kappa) := \begin{cases} \alpha_0(0) & \text{if } \alpha_0(0) \in X_0 \\ \mathrm{div} & \text{otherwise.} \end{cases}$$

Define the multi-function $f_M : X_1 \times \ldots \times X_k \rightrightarrows X_0$ computed by $\mathbf{M}$ as follows: For $x_i \in X_i$ $(0 \le i \le k)$ let $x_0 \in f_M(x_1, \ldots, x_k)$ iff (4a) and (4b):
(a) every maximal computation with first configuration $\mathrm{IC}(x_1, \ldots, x_k)$ is accepting,

(b) there exists an accepting computation $(\kappa^0, \ldots, \kappa^n)$ with first configuration $\kappa^0 = \mathrm{IC}(x_1, \ldots, x_k)$ such that $x_0 = \mathrm{OC}(\kappa^n)$.

For input $(x_1, \ldots, x_k) \in X_1 \times \ldots \times X_k$, the initial configuration has the label l_0, on every tape the head is on position 0, on the input tape i $(1 \leq i \leq k)$ the cell 0 contains the value x_i, and all other tape cells contain the blank symbol $b \in \Gamma$. In every assignment step (2e) every $x \in f(x_{i_1}, \ldots, x_{i_n})$ can be chosen. The result of an accepting computation is the inscription of the cell 0 on Tape 0, which must be in X_0. A value $x \in X_0$ is in $f(x_1, \ldots, x_n)$, if there is an accepting computation with result x and every maximal computation on the same input is accepting.

4. Realization is Closed Under Programming

For multi-functions on multi-represented sets realization is closed under composition, that is, the composition of realizations realizes the composition [20, Theorem 3.1.6] [21, Lemma 20] (see Figure 4).

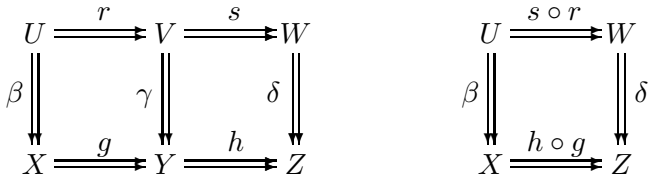

Figure 4: $s \circ r$ realizes $h \circ g$, if r realizes g and s realizes h.

Theorem 4.2 generalizes this fact from simple composition to generalized Turing machines. It is the GTM-version of [21, Theorem 23]. Let $\mathrm{id}_* : \Sigma^* \to \Sigma^*$ be the identity on Σ^*. Then by (2.1), a branching $f :\subseteq X_1 \times \ldots \times X_n \to \Sigma^*$ is a $(\gamma_1, \ldots, \gamma_n, \mathrm{id}_*)$-realization of a branching $g :\subseteq Y_1 \times \ldots \times Y_n \to \Sigma^*$ iff

$$y \in \gamma(x) \cap \mathrm{dom}(g) \implies f(x) = g(y)\,. \tag{4.1}$$

We generalize the concept of realization (Definition 2.1) from functions to generalized Turing machines as follows:

Definition 4.1. Let $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0 \leq i \leq L}, \mathrm{Stm}_M)$ and $\mathbf{N} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (Y_i)_{0 \leq i \leq L}, \mathrm{Stm}_N)$ be generalized Turing machines and let $\gamma_i : X_i \rightrightarrows Y_i$ $(0 \leq i \leq L)$ be generalized multi-representations.

Then "$\mathbf{M}$ is a $(\gamma_i)_{i=0}^L$-realization of $\mathbf{N}$" or "$\mathbf{M}$ realizes $\mathbf{N}$ via $(\gamma_i)_{i=0}^L$", if (1) – (3) for all labels $l \in \mathcal{L}$.

(1) if $\mathrm{Stm}_M(l) \in \{(i, \mathrm{right}, l'),\ (i, \mathrm{left}, l'),\ (i := a, l'),\ (i, \mathrm{if}\ a\ \mathrm{then}\ l',\ \mathrm{else}\ l'')\}$ then $\mathrm{Stm}_M(l) = \mathrm{Stm}_N(l)$,

(2) if $\mathrm{Stm}_M(l) = (i := f(i_1, \ldots, i_n), l')$ then $\mathrm{Stm}_N(l) = (i := g(i_1, \ldots, i_n), l')$ such that $f : X_{i_1} \times \ldots \times X_{i_n} \rightrightarrows X_i$ is a $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \gamma_i)$-realization of $g : Y_{i_1} \times \ldots \times Y_{i_n} \rightrightarrows Y_i$,

(3) if $\mathrm{Stm}_M(l) = (\mathrm{if}\ f(i_1, \ldots, i_n)\ \mathrm{then}\ l',\ \mathrm{else}\ l'')$ then $\mathrm{Stm}_N(l) = (\mathrm{if}\ g(i_1, \ldots, i_n)\ \mathrm{then}\ l',\ \mathrm{else}\ l'')$ such that $f :\subseteq X_{i_1} \times \ldots \times X_{i_n} \to \Sigma^*$ is a $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \mathrm{id}_*)$-realization of $g :\subseteq Y_1 \times \ldots \times Y_k \to \Sigma^*$.

Theorem 4.2. *Let* $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0\le i\le L}, \mathrm{Stm}_M)$ *and* $\mathbf{N} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (Y_i)_{0\le i\le L}, \mathrm{Stm}_N)$ *be generalized Turing machines and let* $\gamma_i : X_i \rightrightarrows Y_i$ *(* $0 \le i \le L$*) be generalized multi-representations.*

If $\mathbf{M}$ *realizes* $\mathbf{N}$ *via* $(\gamma_i)_{i=0}^L$*, then* $f_M : X_1\times\ldots\times X_k \rightrightarrows X_0$ *realizes* $f_N : Y_1\times\ldots\times Y_k \rightrightarrows Y_0$ *via* $(\gamma_1, \ldots, \gamma_k, \gamma_0)$*.*

First we prove a lemma that considers all the details of the generalized Turing machines. It extends the concept of realization for multi-functions in Definition 2.1 to the successor relations $\vdash_M$ and $\vdash_N$. For a configuration $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ of $\mathbf{M}$ and a configuration $\lambda = (\overline{l}, (\overline{\alpha}_0, \overline{m}_0), \ldots, (\overline{\alpha}_L, \overline{m}_L))$ of $\mathbf{N}$ we say "κ realizes λ" iff (4.2) and (4.3) are satisfied:

$$l = \overline{l} \ \wedge \ (\forall i \in \{0, \ldots, L\})\, m_i = \overline{m}_i\,, \tag{4.2}$$

$$(\forall\ i \in \{0, \ldots, L\})\,(\forall\ j \in \mathbb{Z})\,(\alpha_i(j) = \overline{\alpha}_i(j) \in \Gamma \ \vee \overline{\alpha}_i(j) \in \gamma_i \circ \alpha_i(j))\,. \tag{4.3}$$

Lemma 4.3. *Let* $\mathbf{M}$ *be a* $(\gamma_i)_{i=0}^L$*-realization of* $\mathbf{N}$*. If* κ *realizes* λ *and* λ *has a* $\vdash_N$*-successor* λ''*, then*

(1) κ *has a* $\vdash_M$*-successor* κ'' *and*
(2) *if* $\kappa \vdash_M \kappa'$ *then there is some* λ' *such that* $\lambda \vdash_N \lambda'$ *and* κ' *realizes* λ'*.*

Proof. Suppose κ realizes λ. By (4.2) and (4.3) κ and λ can be written as

$$\begin{array}{rcl} \kappa & = & (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L)) \\ \lambda & = & (l, (\overline{\alpha}_0, m_0), \ldots, (\overline{\alpha}_L, m_L)) \end{array}$$

such that $\alpha_i(j) = \overline{\alpha}_i(j) \in \Gamma$ or $\overline{\alpha}_i(j) \in \gamma_i \circ \alpha_i(j))$ for all i, j. By assumption, λ has a successor λ''. Then $l \ne l_f$. We study successively the 6 cases for $\mathrm{Stm}_N(l)$ from Definition 3.2.2. In the last two cases below let

$$\widetilde{x} := (\alpha_{i_1}(m_{i_1}), \ldots, \alpha_{i_n}(m_{i_n})) \quad \text{and} \quad \widetilde{y} := (\overline{\alpha}_{i_1}(m_{i_1}), \ldots, \overline{\alpha}_{i_n}(m_{i_n})).$$

$\mathrm{Stm}_M(l) = (i, \mathrm{right}, l')$:
Then $\mathrm{Stm}_N(l) = (i, \mathrm{right}, l')$. By Definition 3.2.2a $\lambda'' = \lambda[\mathrm{head}_i \leftarrow m_i + 1][\mathrm{label} \leftarrow l']$. Let $\kappa'' := \kappa[\mathrm{head}_i \leftarrow m_i + 1][\mathrm{label} \leftarrow l']$. Then $\kappa \vdash_M \kappa''$ and κ'' realizes λ''. This proves Condition (1) for this case. Since κ'' is the only $\vdash_M$-successor of κ, Lemma 4.3.2 is satisfied for $\kappa' = \kappa''$ and $\lambda' = \lambda''$.

$\mathrm{Stm}_M(l) \in \{(i, \mathrm{left}, l'),\ (i := a, l'),\ (i, \mathrm{if}\ a\ \mathrm{then}\ l',\ \mathrm{else}\ l'')\}$:
In these cases the argument is the same as in the first case.

$\mathrm{Stm}_M(l) = (i := f(i_1, \ldots, i_n), l')$:
Then $\mathrm{Stm}_N(l) = (i := g(i_1, \ldots, i_n), l')$ such that $f : X_{i_1}\times\ldots\times X_{i_n} \rightrightarrows X_i$ is a $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \gamma_i)$-realization of $g : Y_{i_1} \times \ldots \times Y_{i_n} \rightrightarrows Y_i$. Since λ has a successor, $g(\widetilde{y}) \ne \emptyset$. Since f realizes g and κ realizes λ, $\widetilde{x}$ realizes $\widetilde{y}$, hence $f(\widetilde{x}) \ne \emptyset$ by (2.1). Since $f(\widetilde{x}) \ne \emptyset$, κ has a successor by Definition 3.2.2e. This proves Condition (1) for this case lemma.

Let κ' be a successor of κ. Then by Definition 3.2.2e, $\kappa' = \kappa[\mathrm{cell}_i \leftarrow x_0]\,[\mathrm{label} \leftarrow l']$ for some $x_0 \in f(\widetilde{x})$. Since f realizes g, $\widetilde{x}$ realizes $\widetilde{y}$ and $f(\widetilde{x}) \ne \emptyset$, there is some $y_0 \in \gamma_i(x_0) \cap g(\widetilde{y})$ by (2.1). Let $\lambda' := \lambda[\mathrm{cell}_i \leftarrow y_0]\,[\mathrm{label} \leftarrow l']$. Since x_0 realizes y_0, κ' realizes λ'. And since $y_0 \in g(\widetilde{y})$, $\lambda \vdash_N \lambda'$ by Definition 3.2.2e. This proves Condition (2) for this case.

$\mathrm{Stm}_M(l) = (\mathrm{if}\ f(i_1, \ldots, i_n)\ \mathrm{then}\ l',\ \mathrm{else}\ l'')$:
Then $\mathrm{Stm}_N(l) = (\mathrm{if}\ g(i_1, \ldots, i_n)\ \mathrm{then}\ l',\ \mathrm{else}\ l'')$ such that $f : \subseteq X_{i_1} \times \ldots \times X_{i_n} \to \Sigma^*$ is a $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \mathrm{id}_*)$-realization of $g : \subseteq Y_{i_1} \times \ldots \times Y_{i_n} \to \Sigma^*$. Since λ has a successor, either

$g(\widetilde{y}) = 0$ or $g(\widetilde{y}) = 1$. Since f is a $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \mathrm{id}_*)$-realization of g and κ realizes λ, $\widetilde{x}$ realizes $\widetilde{y}$ and either $f(\widetilde{x}) = 0$ or $f(\widetilde{x}) = 1$. By Definition 3.2.2f κ has a successor. This proves Condition (1) for this case.

Let $\kappa \vdash_M \kappa'$. Then by Definition 3.2.2f $\kappa' = \kappa[\mathrm{label} \leftarrow l']$ if $f(\widetilde{x}) = 0$ and $\kappa' = \kappa[\mathrm{label} \leftarrow l'']$ if $f(\widetilde{x}) = 1$. Since f is a $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \mathrm{id}_*)$-realization of g and $\widetilde{x}$ realizes $\widetilde{y}$, either $g(\widetilde{y}) = 0$ or $g(\widetilde{y}) = 1$. Let $\lambda' = \lambda[\mathrm{label} \leftarrow l']$ if $g(\widetilde{y}) = 0$ and $\lambda' = \lambda[\mathrm{label} \leftarrow l'']$ if $g(\widetilde{y}) = 1$. Since $\widetilde{x}$ realizes $\widetilde{y}$, κ' realizes λ' and $\lambda \vdash \lambda'$ by Definition 3.2.2f. This proves Condition (2) for this case. □

We apply Lemma 4.3 to prove Theorem 4.2.

Proof. (Theorem 4.2) First we observe that for configurations κ of $\mathbf{M}$ and λ of $\mathbf{N}$,

$$(\kappa \text{ is accepting} \iff \lambda \text{ is accepting}), \quad \text{if } \kappa \text{ realizes } \lambda. \tag{4.4}$$

Let $x = (x_1, \ldots, x_k) \in X_1 \times \ldots \times X_k$, $y = (y_1, \ldots, y_k) \in Y_1 \times \ldots \times Y_k$ and $y \in \gamma_1 \times \ldots \times \gamma_k(x) \cap \mathrm{dom}(f_N)$. Let $\kappa^0 := \mathrm{IC}_M(x_1, \ldots, x_k)$ and $\lambda^0 := \mathrm{IC}_N(y_1, \ldots, y_k)$. Then κ^0 realizes λ^0. Since $y \in \mathrm{dom}(f_N)$,

$$\text{there is an accepting computation } (\lambda^0, \ldots, \lambda^n) \text{ and} \tag{4.5}$$

$$\text{every maximal computation with first configuration } \lambda^0 \text{ is accepting.} \tag{4.6}$$

By Definitions 2.1 and 3.2.4 it suffices to prove:

(1) there is an accepting computation on $\mathbf{M}$ with first configuration κ^0, and
(2) every maximal computation on $\mathbf{M}$ with first configuration κ^0 is an accepting computation $(\kappa^0, \ldots, \kappa^n)$ such that there is an accepting computation $(\lambda^0, \ldots, \lambda^n)$ such that κ^n realizes λ^n.

Proof of (1): We know that κ^0 realizes λ^0. For induction suppose $(\kappa^0, \ldots, \kappa^m)$ is a computation on $\mathbf{M}$ and $(\lambda^0, \ldots, \lambda^m)$ is a computation on $\mathbf{N}$ such that κ^m realizes λ^m. Suppose λ^m has a successor. By Lemma 4.3.1 κ^m has a successor κ^{m+1} and by Lemma 4.3.2 there is some successor λ^{m+1} of λ^m such that κ^{m+1} realizes λ^{m+1}. Then $(\kappa^0, \ldots, \kappa^{m+1})$ and $(\lambda^0, \ldots, \lambda^{m+1})$ are computations such that κ^{m+1} realizes λ^{m+1}. By (4.6) this inductive process must end with an accepting computation $(\lambda^0, \ldots, \lambda^n)$. For the corresponding computation $(\kappa^0, \ldots, \kappa^n)$ on $\mathbf{M}$, κ^n realizes λ^n. By (4.4), this computation is accepting.

Proof of (2): Let $(\kappa^0, \kappa^1, \ldots)$ be a maximal computation on M. Then κ^0 realizes λ^0. Assume, for the computation $(\kappa^0, \ldots, \kappa^m)$ we have determined a computation $(\lambda^0, \ldots, \lambda^m)$ on $\mathbf{N}$ such that κ^m realizes λ^m.

Suppose, λ^m has a successor. Then, by Lemma 4.3, κ^m has a successor as well. Therefore, $(\kappa^0, \ldots, \kappa^m)$ is not maximal, hence κ^{m+1} exists. By Lemma 4.3.2, λ^m has a successor λ^{m+1} such that κ^{m+1} realizes λ^{m+1}.

By (4.6) this process must stop at some n such that $(\kappa^0, \ldots, \kappa^n)$ is an initial part of our maximal computation and $(\lambda^0, \ldots, \lambda^n)$ is accepting. Since κ^n realizes λ^n, κ^n is accepting by (4.4). This proves 2. □

5. Computable Functions on Σ^* and Σ^ω are Closed Under Programming

Suppose, in Definition 3.1, $X_i = \Sigma^\omega$ for all i and all the functions f in Definitions 3.1.5e and 3.1.5f are computable. We want to show that $f_M :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ is computable. We solve the problem by reduction to generating functions and sets on Σ^*.

Computable functions $f :\subseteq (\Sigma^\omega)^k \to \Sigma^*$ or $f :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ can be generated by monotone computable word functions [20, Def 2.1.10, Lemma 2.1.11]. Here we use the slightly modified Definition 2 from [21].

Definition 5.1.

(1) Call a function $h :\subseteq (\Sigma^*)^k \to \Sigma^*$ *monotone-constant*, iff

$$(h(y)\downarrow \text{ and } y \sqsubseteq y') \implies (h(y')\downarrow \text{ and } h(y) = h(y'))\,.$$

For a monotone-constant function h define $T_*(h) :\subseteq (\Sigma^\omega)^k \to \Sigma^*$ by

$$T_*(h)(x) = w \iff (\exists y \in (\Sigma^*)^k)\,(y \sqsubseteq x \ \wedge\ h(y) = w). \tag{5.1}$$

(2) Call a function $h :\subseteq (\Sigma^*)^k \to \Sigma^*$ *monotone*, iff

$$(h(y)\downarrow \text{ and } y \sqsubseteq y') \implies (h(y')\downarrow \text{ and } h(y) \sqsubseteq h(y'))\,.$$

For a monotone function h define $T_\omega(h) :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ by

$$T_\omega(h)(x) = q \iff q = \sup\nolimits_{\sqsubseteq}\{h(y) \mid y \sqsubseteq x \text{ and } h(y)\downarrow\}\,. \tag{5.2}$$

Notice that $T_*(h)$ and $T_\omega(h)$ are well-defined by the "generating function" h. By Lemma 5.2, Turing computable functions $f :\subseteq (\Sigma^\omega)^k \to \Sigma^*$ or $f' :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ can be generated by computable word functions $h :\subseteq (\Sigma^*)^k \to \Sigma^*$ which are monotone-constant or monotone, respectively. We include the continuous versions.

Lemma 5.2. [20, 21]

(1) *A function $f :\subseteq (\Sigma^\omega)^k \to \Sigma^*$ is continuous with open domain, iff $f = T_*(h)$ for some monotone-constant function $h :\subseteq (\Sigma^*)^k \to \Sigma^*$.*
(2) *A function $f :\subseteq (\Sigma^\omega)^k \to \Sigma^*$ is Turing computable, iff $f = T_*(h)$ for some Turing computable monotone-constant function $h :\subseteq (\Sigma^*)^k \to \Sigma^*$.*
(3) *A function $f :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ is continuous with G_δ-domain, iff $f = T_\omega(h)$ for some monotone function $h :\subseteq (\Sigma^*)^k \to \Sigma^*$.*
(4) *A function $f :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ is Turing computable, iff $f = T_\omega(h)$ for some Turing computable monotone function $h :\subseteq (\Sigma^*)^k \to \Sigma^*$.* □

Properties 2 and 4 are (essentially) [20, Lemma 2.1.11]. The proofs show how Type-2 machines can be converted to "generating" Turing machines and conversely. For proving the continuous versions we can use machines with an oracle $B\subseteq\Sigma^*$. For the next proofs we extend the prefix relation $\sqsubseteq$ on $\Sigma^*\cup\Sigma^\omega$ straightforwardly to $\Sigma^*\cup\Sigma^\omega\cup\Gamma$ and to configurations of machines operating on the sets Σ^* or Σ^ω. For $u, v \in \Sigma^* \cup \Sigma^\omega \cup \Gamma$ and configurations $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ and $\kappa' = (l', (\alpha'_0, m'_0), \ldots, (\alpha'_L, m'_L))$ of generalized Turing machines $\mathbf{M}$ and $\mathbf{N}$, respectively, define:

$$u \sqsubseteq_1 v :\iff u = v \in \Gamma \text{ or } (u, v \in \Sigma^* \cup \Sigma^\omega \text{ and } u \sqsubseteq v)\,,$$

$$\kappa \sqsubseteq_2 \kappa' :\iff (\forall\, 1 \le i \le L)(\forall\, j \in \mathbb{Z})\,)(l = l',\ m_i = m'_i,\ \alpha_i(j) \sqsubseteq_1 \alpha'_i(j)).$$

Lemma 5.3. *Let $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0\le i\le L}, \mathrm{Stm}_M)$ be a generalized Turing machine such that $X_i = \Sigma^*$ for $0 \le i \le L$. For every $l \in \mathcal{L}$ let $f :\subseteq (\Sigma^*)^n \to \Sigma^*$ be monotone if $\mathrm{Stm}_M(l) = (i := f(i_1, \ldots, i_n), l')$ and let $f :\subseteq (\Sigma^*)^n \to \Sigma^*$ be monotone constant if $\mathrm{Stm}_M(l) = (\text{if } f(i_1, \ldots, i_n) \text{ then } l', \text{ else } l'')$. Then $f_M :\subseteq (\Sigma^*)^k \to \Sigma^*$ is monotone.*

Proof. Since all the functions used in $\mathbf{M}$ are single-valued, the successor relation on configurations is a partial function, which we denote by S. First, we prove that for all configurations κ, κ' of $\mathbf{M}$:

$$(S(\kappa)\downarrow \wedge \kappa \sqsubseteq_2 \kappa') \implies (S(\kappa')\downarrow \wedge (S(\kappa) \sqsubseteq_2 S(\kappa'))\,. \tag{5.3}$$

If $\kappa \sqsubseteq_2 \kappa'$ then κ and κ' have the same labels and the same head positions. Therefore, they can be written as $\kappa = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$ and $\kappa' = (l, (\alpha'_0, m_0), \ldots, (\alpha'_L, m_L))$ such that $\alpha_i(j) = \alpha'_i(j) \in \Gamma$ or $\alpha_i(j) \sqsubseteq \alpha'_i(j) \in \Sigma^*$ for all i, j. The successor function S changes κ and κ' only locally. We consider the six alternatives from Definition 3.2.

$\mathbf{Stm_M(l) = (i, right, l')}$:
Then $S(\kappa) = \kappa[\text{head}_i \leftarrow m_i + 1]\,[\text{label} \leftarrow l']$ and $S(\kappa') = \kappa'[\text{head}_i \leftarrow m_i + 1]\,[\text{label} \leftarrow l']$. Obviously $S(\kappa) \sqsubseteq_2 S(\kappa')$.

$\mathbf{Stm_M(l) \in \{(i, \text{left}, l'),\ (i := a, l'),\ (i, \text{if } a \text{ then } l', \text{ else } l'')\}}$:
In these cases the argument is the same as in the first case.

$\mathbf{Stm_M(l) = (i := f(i_1, \ldots, i_n), l')}$:
The statement can change only the label and the inscription under the head of Tape i. Since $S(\kappa)$ exists, $x := f(x_{i_1}, \ldots, x_{i_n})$ exists, where $x_{i_j} = \alpha_j(m_j) \in \Sigma^*$ for $1 \le j \le n$ (see Definition 3.2). Since $\kappa \sqsubseteq_2 \kappa'$, $x_{i_j} \sqsubseteq x'_{i_j} := \alpha'_j(m_j) \in \Sigma^*$ $(1 \le j \le n)$. Since f is monotone, $f(x'_{i_1}, \ldots, x'_{i_n})$ exists and $x = f(x_{i_1}, \ldots, x_{i_n}) \sqsubseteq f(x'_{i_1}, \ldots, x'_{i_n}) = x'$. Since $\kappa \sqsubseteq_2 \kappa'$ and $S(\kappa) = \kappa[\text{cell}_i \leftarrow x]\,[\text{label} \leftarrow l']$ and $S(\kappa') = \kappa'[\text{cell}_i \leftarrow x']\,[\text{label} \leftarrow l']$, $S(\kappa) \sqsubseteq_2 S(\kappa')$.

$\mathbf{Stm_M(l) = (\text{if } f(i_1, \ldots, i_n) \text{ then } l', \text{else } l'')}$:
The statement changes only the labels (or cannot be applied). Since $S(\kappa)$ exists by assumption, $f(x_{i_1}, \ldots, x_{i_n}) \in \{0, 1\} \subseteq \Sigma^*$ exists, where $x_{i_j} = \alpha_j(m_j) \in \Sigma^*$ for $1 \le j \le n$ (see Definition 3.2). Since $\kappa \sqsubseteq_2 \kappa'$, $x_{i_j} \sqsubseteq x'_{i_j} := \alpha'_j(m_j) \in \Sigma^*$ $(1 \le j \le n)$. Since f is monotone constant, $f(x'_{i_1}, \ldots, x'_{i_n})$ exists and $f(x_{i_1}, \ldots, x_{i_n}) = f(x'_{i_1}, \ldots, x'_{i_n})$. By Definition 3.2, also the labels of $S(\kappa)$ and $S(\kappa')$ are the same, hence $S(\kappa) \sqsubseteq_2 S(\kappa')$.

This proves (5.3).

Now suppose $w = (w_1, \ldots, w_k) \sqsubseteq (w'_1, \ldots, w'_k) = w'$. Then $\text{IC}_M(w) \sqsubseteq_2 \text{IC}_M(w')$ (Definition 3.2). Suppose $f_M(w)$ exists. Then for some n, $S^n \circ \text{IC}_M(w)$ exists and is an accepting configuration such that $f_M(w) = \alpha_0(0)$. From (5.3) by induction for all $k \le n$, $S^k \circ \text{IC}_M(w')$ exists and $S^k \circ \text{IC}_M(w) \sqsubseteq_2 S^k \circ \text{IC}_M(w')$. Since $S^n \circ \text{IC}_M(w) \sqsubseteq_2 S^n \circ \text{IC}_M(w')$ and $S^n \circ \text{IC}_M(w)$ is accepting, $S^n \circ \text{IC}_M(w')$ is accepting. Then, $f_M(w)$, the word on (Tape 0, Cell 0) of $S^n \circ \text{IC}_M(w)$ is a prefix of $f_M(w')$, the word on (Tape 0, Cell 0) of $S^n \circ \text{IC}_M(w')$, hence $f_M(w) \sqsubseteq f_M(w')$. Therefore, f_M is monotone. □

Let $\mathbf{M}$ be a generalized Turing machine on generating word functions and let $\mathbf{N}$ be the corresponding generalized Turing machine on generated functions on Σ^ω. Then $f_M :\subseteq (\Sigma^*)^k \to \Sigma^*$ generates an extension of $f_N :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$:

Theorem 5.4. *Let* $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0 \le i \le L}, \text{Stm}_M)$ *and* $\mathbf{N} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (Y_i)_{0 \le i \le L}, \text{Stm}_N)$ *be generalized Turing machines such that* $X_i = \Sigma^*$ *and* $Y_i = \Sigma^\omega$ *for* $0 \le i \le L$ *and all functions occurring in* $\mathbf{M}$ *or* $\mathbf{N}$ *are single-valued. Assume that for all labels* $l \in \mathcal{L}$,

(1) *if* $\text{Stm}_M(l) \in \{(i, \text{right}, l'),\ (i, \text{left}, l'),\ (i := a, l'),\ (i, \text{if } a \text{ then } l', \text{ else } l'')\}$ *then* $\text{Stm}_M(l) = \text{Stm}_N(l)$,

(2) *if* $\mathrm{Stm}_M(l) = (i := f(i_1,\dots,i_n), l')$ *then* f *is monotone and* $\mathrm{Stm}_N(l) = (i := g(i_1,\dots,i_n), l')$ *such that* $T_\omega(f)$ *extends* g,
(3) *if* $\mathrm{Stm}_M(l) = (\text{if } f(i_1,\dots,i_n) \text{ then } l', \text{ else } l'')$ *then* f *is monotone-constant and* $\mathrm{Stm}_N(l) = (\text{if } g(i_1,\dots,i_n) \text{ then } l', \text{ else } l'')$ *such that* $T_*(f)$ *extends* g.

Then $T_\omega(f_M)$ *extends* $f_N :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$.

Proof. We must prove that for all $q \in \mathrm{dom}(f_N)$,

$$f_N(q) = T_\omega(f_M)(q) = \sup_\sqsubseteq\{f_M(u) \mid u \in (\Sigma^*)^k, u \sqsubseteq q \text{ and } f_M(u)\downarrow\}\,. \tag{5.4}$$

Since all the functions used in **M** and **N** are single-valued, the successor relations on configurations are functions, which we denote by S for both machines. For a word $w \in \Sigma^*$ let $|w|$ denote its length. For a configuration κ for **M** define the precision by

$$P(\kappa) := \min\{|\alpha_i(j)| \mid 0 \le i \le L,\ j \in \mathbb{Z},\ \alpha_i(j) \in \Sigma^*\}\,.$$

For $q = (q_1,\dots,q_k) \in (\Sigma^\omega)^k$ and $e \in \mathbb{N}$ let $q^{<e} := (w_1,\dots,w_k)$ where w_i is the prefix of q_i of length e.

Proposition 5.5. *Suppose,* $q = (q_1,\dots,q_k) \in \mathrm{dom}(f_N) \subseteq (\Sigma^\omega)^k$. *Then for all* m *such that* $\lambda := S^m \circ \mathrm{IC}_N(q)$ *exists:*

$$(\forall d)(\exists \overline{e})(\forall e \ge \overline{e})(\kappa := S^m \circ \mathrm{IC}_M(q^{<e})\downarrow,\ \kappa \sqsubseteq_2 \lambda,\ P(\kappa) \ge d) \tag{5.5}$$

(where d, $\overline{e}$, $e \in \mathbb{N}$*). This means that for sufficiently precise input,* κ *exists and approximates* λ *with at least precision* d.

Proof. (Proposition 5.5) We prove (5.5) by induction on $m \in \mathbb{N}$.

$\boldsymbol{m = 0}$: For $d \in \mathbb{N}$ choose $\overline{e} := d$. Then for $e \ge \overline{e}$ by Definition 3.2.4, $S^0 \circ \mathrm{IC}_M(q^{<e}) \sqsubseteq_2 S^0 \circ \mathrm{IC}_N(q)$ and $P(S^0 \circ \mathrm{IC}_M(q^{<e})) = e \ge d$.

$\boldsymbol{m \Longrightarrow m+1}$: Assume that the statement has been proved for m and assume that $S^{m+1} \circ \mathrm{IC}_N(q)$ exists. Then $S^m \circ \mathrm{IC}_N(q)$ exists and can be written as

$$\lambda \ := \ S^m \circ \mathrm{IC}_N(q) = (l, (\beta_0, m_0), \dots, (\beta_L, m_L))\,. \tag{5.6}$$

Let $d \in \mathbb{N}$. We consider the 6 alternatives for $\mathrm{Stm}_N(l)$ from Definition 3.2. Notice that the successor functions S of **M** and **N** change configurations only locally.

$\boldsymbol{\mathrm{Stm}_N(l) = (i, \mathrm{right}, l')}$:
By assumption, there is some $\overline{e} \in \mathbb{N}$ such that for all $e \ge \overline{e}$, $\kappa := S^m \circ \mathrm{IC}_M(q^{<e})$ exists, $\kappa \sqsubseteq_2 \lambda$ and $P(\kappa) \ge d$. We show that we can choose this number $\overline{e}$ for $m+1$ and d as well. Since $\kappa \sqsubseteq_2 \lambda$, κ can be written as

$$\kappa = S^m \circ \mathrm{IC}_M(q^{<e}) = (l, (\alpha_0, m_0), \dots, (\alpha_L, m_L))$$

such that for all i and j, $\alpha_i(j) = \beta_i(j) \in \Gamma$ or $\alpha_i(j) \sqsubseteq \beta_i(j)$ (where $\alpha_i(j) \in \Sigma^*$ and $\beta_i(j) \in \Sigma^\omega$). By the condition in Theorem 5.4.1, $\mathrm{Stm}_M(l) = \mathrm{Stm}_N(l) = (i, \mathrm{right}, l')$. Therefore,

$$\begin{aligned} S(\lambda) &= \lambda[\mathrm{head}_i \leftarrow m_i + 1]\,[\mathrm{label} \leftarrow l']\,, \\ S(\kappa) &= \kappa[\mathrm{head}_i \leftarrow m_i + 1]\,[\mathrm{label} \leftarrow l']\,. \end{aligned}$$

Since on λ and κ the successors S operate in the same way depending at most on tape cells containing elements of Γ and changing at most such tape cells, $\kappa \sqsubseteq_2 \lambda$ implies $S \circ \kappa \sqsubseteq_2 S \circ \lambda$ and $P(S \circ \kappa) = P(\kappa) \ge d$.

$\mathbf{Stm_N(l) \in \{(i, left, l'),\ (i := a, l')\ (i, if\ a\ then\ l', else\ l'')\}}$:
The arguments in these cases are the same as in the first case.

$\mathbf{Stm_N(l) = (i := g(i_1, \ldots, i_n), l')}$:
By the condition in Theorem 5.4.2, $\mathrm{Stm}_M(l) = (i := f(i_1, \ldots, i_n), l')$ such that $T_\omega(f)$ extends g.

Let $s := (s_1, \ldots, s_n) \in (\Sigma^\omega)^n$ such that $s_j = \beta_{i_j}(m_{i_j})$ is the content of the cell under the head of Tape i_j of the configuration λ (see (5.6)). Since $S^{m+1} \circ \mathrm{IC}_N(q) = S(\lambda)$ exists, $s \in \mathrm{dom}(g)$. Since $T_\omega(f)$ extends g, by the sup-condition in Definition 5.1.2

$$(\exists \overline{b})(\forall b \geq \overline{b})(f(s^{<b}) \downarrow,\quad f(s^{<b}) \sqsubseteq g(s) \text{ and } |f(s^{<b})| \geq d)\,. \tag{5.7}$$

By induction as a special case of (5.5), for $\max(\overline{b}, d)$ there is some $\overline{e}$ such that

$$(\forall e \geq \overline{e})(\kappa := S^m \circ \mathrm{IC}_M(q^{<e}) \downarrow,\quad \kappa \sqsubseteq_2 \lambda \text{ and } P(\kappa) \geq \max(\overline{b}, d))\,. \tag{5.8}$$

We show that this constant $\overline{e}$ is appropriate for $m+1$ and d in (5.5). Let $e \geq \overline{e}$, $\kappa := S^m \circ \mathrm{IC}_M(q^{<e})$ and $\kappa' := S^{m+1} \circ \mathrm{IC}_M(q^{<e}) = S(\kappa)$. Since $\kappa \sqsubseteq_2 \lambda$, κ can be written as (see (5.6))

$$\kappa = S^m \circ \mathrm{IC}_M(q^{<e}) = (l, (\alpha_0, m_0), \ldots, (\alpha_L, m_L))$$

such that for all $0 \leq j \leq L$ and i', $\alpha_j(i') = \beta_j(i') \in \Gamma$ or $\alpha_j(i') \sqsubseteq \beta_j(i')$ (where $\alpha_j(i') \in \Sigma^*$ and $\beta_j(i') \in \Sigma^\omega$). Let $u := (u_1, \ldots, u_k)$ where $u_j := \alpha_{i_j}(m_{i_j})$. Then $u \sqsubseteq s$. By Definition 3.2

$$\begin{array}{rcl} S(\kappa) & = & \kappa[\mathrm{cell}_i \leftarrow v]\,[\mathrm{label} \leftarrow l']\,, \\ S(\lambda) & = & \lambda[\mathrm{cell}_i \leftarrow q']\,[\mathrm{label} \leftarrow l']\,, \end{array} \tag{5.9}$$

where $v = f(u)$ and $q' = g(s)$. By (5.5) we must prove:

$$\kappa' := S^{m+1} \circ \mathrm{IC}_M(q^{<e}) \downarrow,\ \kappa' \sqsubseteq_2 S(\lambda) \text{ and } P(\kappa') \geq d\,. \tag{5.10}$$

Since $P(\kappa) \geq \overline{b}$, $s^{<\overline{b}} \sqsubseteq u$. Since $f(s^{<\overline{b}}) \downarrow$ by (5.7) and f is monotone, $f(u)$ exists. Therefore, $\kappa' = S(\kappa)$ exists. Then $S(\kappa)$ and $S(\lambda)$ can be written as

$$\begin{array}{rcl} S(\kappa) & = & (l', (\alpha'_0, m_0), \ldots, (\alpha'_L, m_L))\,, \\ S(\lambda) & = & (l', (\beta'_0, m_0), \ldots, (\beta'_L, m_L))\,. \end{array} \tag{5.11}$$

$S(\kappa)$ differs from κ only on Cell i, the cell under the head of Tape i, and $S(\lambda)$ differs from λ only on Cell i, the cell under the head of Tape i.

Since $u \sqsubseteq s$ and $T_\omega(f)$ extends g, by (5.9), $\alpha'_i(m_i) = f(u) \sqsubseteq g(s) = \beta'_i(m_i)$. For all $(j, i') \neq (i, m_i)$ by $\kappa \sqsubseteq_2 \lambda$ (5.8) $\alpha'_j(i') = \alpha_j(i') \sqsubseteq_1 \beta_j(i') = \beta'_j(i')$. Therefore, $S(\kappa) \sqsubseteq_2 S(\lambda)$.

By (5.8), $|u_j| \geq \overline{b}$ for $1 \leq j \leq n$, hence $s^{<\overline{b}} \sqsubseteq u$, since $u \sqsubseteq s$. By (5.7) and monotonicity of f, $|\alpha'_i(m_i)| = |f(u)| \geq |f(s^{<\overline{b}})| \geq d$. For all $(j, i') \neq (i, m_i)$ such that $\alpha'_j(i') \in \Sigma^*$, $|\alpha'_j(i')| = |\alpha_j(i')| \geq d$, since $P(\kappa) \geq d$ by (5.8). Therefore, $P(\kappa') \geq d$.

This proves (5.10) and finishes the case $\mathrm{Stm}_N(l) = (i := g(i_1, \ldots, i_n), l')$.

$\mathbf{Stm_N(l) = (if\ g(i_1, \ldots, i_n)\ then\ l', else\ l'')}$:
The proof can be obtained by straightforward modification of the proof of the previous case. □(Proposition 5.5)

It remains to prove (5.4). Suppose, $f_N(q)$ exists. Then for some $m \in \mathbb{N}$, $\lambda := S^m \circ \mathrm{IC}_N(q)$ exists, λ is a final configuration and $\mathrm{OC}(\lambda) = f_N(q)$. Let $d \in \mathbb{N}$. By Proposition 5.5 there is some $\overline{e} \in \mathbb{N}$ such that $\kappa := S^m \circ \mathrm{IC}_M(q^{<\overline{e}})$ exists, $\kappa \sqsubseteq_2 \lambda$ and $P(\kappa) \geq d$. Since $\kappa \sqsubseteq_2 \lambda$, also κ is a final configuration and $f_M(q^{<\overline{e}}) = \mathrm{OC}(\kappa) \sqsubseteq \mathrm{OC}(\lambda) = f_N(q)$.

Furthermore, $|f_M(q^{<\overline{e}})| \geq d$, since $P(\kappa) \geq d$. Since f_M is monotone by Lemma 5.3, $f_N(q) = \sup_{\sqsubseteq}\{f_M(q^{<e}) \mid e \in \mathbb{N}\}$. Since for all $u \in (\Sigma^*)^k$ with $u \sqsubseteq q$ there is some e such that $u \sqsubseteq q^{<e}$, $\sup_{\sqsubseteq}\{f_M(q^{<e}) \mid e \in \mathbb{N}\} = \sup_{\sqsubseteq}\{f_M(u) \mid u \sqsubseteq q\} = T_\omega(f_M)$.

Therefore, $T_\omega(f_M)$ extends $f_N :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$. □

If all functions on Σ^* used in the machine $\mathbf{M}$ from Theorem 5.4 are computable, then f_M is a computable word function.

Lemma 5.6. *Let $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (X_i)_{0\leq i\leq L}, \mathrm{Stm}_M)$ be a generalized Turing machine such that $X_i = \Sigma^*$ for $0 \leq i \leq L$ and all functions on Σ^* used in the machine are computable. Then $f_M :\subseteq (\Sigma^*)^k \to \Sigma^*$ is computable.*

Proof. From the generalized Turing machine $\mathbf{M}$ an ordinary Turing machine $\mathbf{N}$ computing f_M can be constructed by standard techniques. □

By the next theorem the continuous as well as the computable functions on Σ^ω are closed under programming.

Theorem 5.7. *Let $\mathbf{N} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (Y_i)_{0\leq i\leq L}, \mathrm{Stm}_N)$ be a generalized Turing machine on Σ^ω, that is, $Y_i = \Sigma^\omega$ for $0 \leq i \leq L$. If all the functions on Σ^ω used in the machine $\mathbf{N}$*

(1) *are continuous, then $f_N :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ is continuous,*
(2) *are computable, then $f_N :\subseteq (\Sigma^\omega)^k \to \Sigma^\omega$ is computable.*

Proof. (1) Every function used in $\mathbf{N}$ is generated by a monotone or monotone constant word function (Lemma 5.2). Let $\mathbf{M}$ be the machine constructed with these word functions that satisfies the conditions from Theorem 5.4. Then $T_\omega(f_M)$ extends f_N. By Lemma 5.2, f_N is continuous.

(2) In addition to Case (1) there are even computable word functions. Again the function f_M generates f_N. By Lemma 5.6, f_M is computable, hence f_N is computable by Lemma 5.2. □

The generalization from Σ^ω to Σ^* and Σ^ω is straightforward.

Corollary 5.8. *Theorem 5.7 holds accordingly, if $Y_i \in \{\Sigma^*, \Sigma^\omega\}$ for $0 \leq i \leq L$.*

Proof. Define a standard representation $\beta :\subseteq \Sigma^\omega \to \Sigma^*$ of Σ^* by $\beta(\iota(w)0^\omega) := w$ (where $\iota(a_1 \dots a_n) := 110a_1 0 \dots 0a_n 011$,[20, Definition 2.1.7]). For Y_j let $\delta_j := \mathrm{id}_{\Sigma^\omega}$ if $Y_j = \Sigma^\omega$ and $\delta_j := \beta$ if $Y_j = \Sigma^*$. Then a function $f :\subseteq Y_{i_1} \times \ldots \times Y_{i_n} \to Y_{i_0}$ is computable, iff it is $(\delta_{i_1}, \ldots, \delta_{i_n}, \delta_{i_0})$-computable by a realization on Σ^ω. Let $\mathbf{M}$ be a machine obtained from $\mathbf{N}$ by replacing every function f on Σ^ω and Σ^* by a computable realizing function on Σ^ω. Then $\mathbf{M}$ realizes $\mathbf{N}$, hence f_M realizes f_N by Theorem 4.2. Since f_M is computable by Theorem 5.7, f_N is computable. For "continuous" the argument is the same. □

6. Machines on Represented Sets, the Main Results

After the preparations in Sections 4 and 5 we can easily prove our main results, Theorems 6.2 and 6.6. Since the computable functions on Σ^ω are closed under composition, the composition of computable functions on represented sets is computable [20, Theorem 3.1.6]. The following main result of this article generalizes this observation from single-valued to multi-valued functions and representations and from composition to generalized Turing machines.

Definition 6.1. Let $\mathbf{P} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (Z_i)_{0\leq i\leq L}, \mathrm{Stm}_P)$ be a generalized Turing machine and for each i, $0 \leq i \leq L$, let $\delta_i : \Sigma^\omega \rightrightarrows Z_i$ be a multi-representation. The machine is called $(\delta_i)_{0\leq i\leq L}$-computable, iff

(1) for every statement "$(i := f(i_1, \ldots, i_n), l')$" in $\mathbf{P}$
the multi-function f is $(\delta_{i_1}, \ldots, \delta_{i_n}, \delta_i)$-computable and
(2) for every statement "(if $f(i_1, \ldots, i_n)$ then l', else l'')" in $\mathbf{P}$
the partial function f is $(\delta_{i_1}, \ldots, \delta_{i_n}, \mathrm{id}_*)$-computable.

"$(\delta_i)_{0\leq i\leq L}$-continuous" is defined in the same way with "continuous" replacing "computable".

Theorem 6.2. *Let $\mathbf{P}$ be a generalized Turing machine with k input tapes and for $0 \leq i \leq L$ let δ_i be a multi-representation of Z_i such that the machine is $(\delta_i)_{0\leq i\leq L}$-computable. Then the function f_P computed by the machine is $(\delta_1, \ldots, \delta_k, \delta_0)$-computable.*

Correspondingly with "continuous" instead of "computable".

Proof. Case "continuous": There is a generalized Turing machine $\mathbf{M}$ on Σ^ω containing only continuous functions that realizes $\mathbf{P}$ via $(\delta_i)_{0\leq i\leq L}$ (replace every function in $\mathbf{P}$ by a realizing function on Σ^ω). By Theorem 4.2, f_M realizes f_P via $(\delta_1, \ldots, \delta_k, \delta_0)$. By Theorem 5.7, f_M is continuous. Therefore, f_P is $(\delta_1, \ldots, \delta_k, \delta_0)$-continuous.

The case "computable" can be proved in the same way. □

Corollary 6.3. *Theorem 6.2 remains true if in Definition 6.1 and in the theorem some multi-representations $\delta_j : \Sigma^\omega \rightrightarrows Z_j$ are replaced by multi-notations $\nu_j : \Sigma^* \rightrightarrows Z_j$.*

Proof. For every multi-notation $\nu : \Sigma^* \rightrightarrows X$ there is a multi-representation $\delta : \Sigma^\omega \rightrightarrows X$ such that $\nu \equiv \delta$, and equivalent multi-notations/representations of a set X induce the same computability and continuity on X [21, Section 8]. Replace every multi-notation by an equivalent multi-representation and apply Theorem 6.2. In the final result return to the multi-notations. □

In applications, generalized representations are already used informally, whenever defining explicitly Type-2 Turing machines for realizing functions on Σ^ω is too cumbersome.

Example 6.4. Let SRI be the set of all sequences of intervals $[a; b] \subseteq \mathbb{R}$ with rational end points $a < b$. Let $\gamma :\subseteq \Sigma^\omega \to \mathrm{SRI}$ be a canonical representation and define a generalized representation $\delta :\subseteq \mathrm{SRI} \to \mathbb{R}$ of the real numbers by $\delta(I_0, I_1, \ldots) = x \iff \{x\} = \bigcap_n I_n$. Then $\delta \circ \gamma :\subseteq \Sigma^\omega \to \mathbb{R}$ is a representation that is equivalent to the standard representation ρ of the real numbers [20, Chapter 4]. For proving that addition on the real numbers is computable via $\delta \circ \gamma$ consider the following binary function f_+ on SRI:

$$f_+((I_0, I_1, \ldots), (J_0, J_1, \ldots)) := (I_0 + J_0, I_1 + J_1, \ldots).$$

The experienced reader knows that the function f_+ is (γ, γ, γ)-computable and a simple proof shows that f_+ is a (δ, δ, δ)-realization of addition. By the next lemma from [21] we may conclude that addition is computable via $\delta \circ \gamma$. □

For multi-functions $\gamma : X \rightrightarrows Y$ and $\delta : Y \rightrightarrows Z$ the "relational" composition $\delta \odot \gamma$ is defined by

$$z \in \delta \odot \gamma(x) \iff (\exists\, y)\, (y \in \gamma(x) \ \wedge \ z \in \delta(y)), \tag{6.1}$$

see [21, Sections 3 and 6]. If γ and δ are multi-representations, an element $x \in X$ should be considered as a name of z via the combination of γ and δ, if there is some $y \in Y$ such that x is a γ-name of y and y is a δ-name of z, that is, $y \in \gamma(x)$ and $z \in \delta(y)$, hence

$z \in (\delta \odot \gamma)(x)$. Therefore, we use relational composition for multi-representations. Notice that for single-valued γ (as in Example 6.4), $\delta \odot \gamma = \delta \circ \gamma$.

Realization is downwards transitive. If h realizes g and g realizes f then h realizes f w.r.t. the composed representations (Figure 5).

Lemma 6.5 ([21])**.** *Let $\gamma : X \rightrightarrows Y$, $\delta : Y \rightrightarrows Z$, $\gamma' : U \rightrightarrows V$ and $\delta' : V \rightrightarrows W$ be generalized multi-representations. If $h : X \rightrightarrows U$ is a (γ, γ')-realization of $g : Y \rightrightarrows V$ and $g : Y \rightrightarrows V$ is a (δ, δ')-realization of $f : Z \rightrightarrows W$, then $h : X \rightrightarrows U$ is a $(\delta \odot \gamma, \delta' \odot \gamma')$-realization of $f : Z \rightrightarrows W$.* □

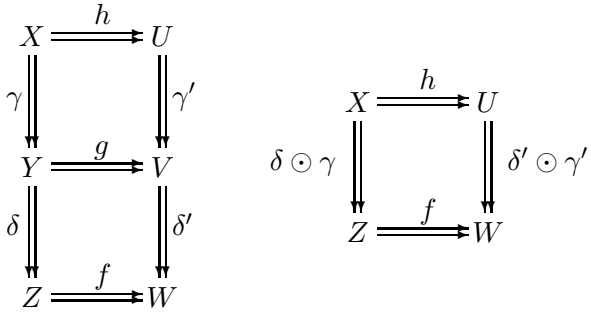

Figure 5: Realization is downwards transitive.

In Example 6.4, $\mathbb{R}$ can be called the set of "abstract" data, Σ^ω the set of "concrete" data and SRI the set of data of "intermediate abstraction". If computability on data of intermediate abstraction is well understood, it may be of advantage to use them as names in generalized representations. The following theorem generalizes Theorem 6.2. It shows that the function f_P computed by a generalized Turing machine $\mathbf{P}$ containing only functions realized by computable functions on data of intermediate abstraction is computable.

Theorem 6.6. *Let $\mathbf{P} = (\mathcal{L}, l_0, l_f, \Gamma, b, k, L, (Z_i)_{0 \le i \le L}, \mathrm{Stm}_P)$ be a generalized Turing machine. For each i, $0 \le i \le L$, let $\delta_i : Y_i \rightrightarrows Z_i$ be a generalized multi-representation and let $\gamma_i : \Sigma^\omega \rightrightarrows Y_i$ be a multi-representation. Suppose,*

(1) *for every statement "$(i := f(i_1, \ldots, i_n), l')$" in $\mathbf{P}$ the multi-function f has a realization g via $(\delta_{i_1}, \ldots, \delta_{i_n}, \delta_i)$ that is $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \gamma_i)$-computable, and*
(2) *for every statement "$(\text{if } f(i_1, \ldots, i_n) \text{ then } l', \text{ else } l'')$" in $\mathbf{P}$ the partial function f has a realization g via $(\delta_{i_1}, \ldots, \delta_{i_n}, \mathrm{id}_*)$ that is $(\gamma_{i_1}, \ldots, \gamma_{i_n}, \mathrm{id}_*)$-computable.*

Let $\mathbf{M}$ be a machine obtained from $\mathbf{P}$ by replacing every function f by some function g computable w.r.t the γ_j realizing f via the δ_j as described in (1) and (2). Then

(a) *f_M is $(\gamma_1, \ldots, \gamma_k, \gamma_0)$-computable,*
(b) *f_M realizes f_P via $(\delta_1, \ldots, \delta_k, \delta_0)$,*
(c) *f_P is $(\delta_1 \odot \gamma_1, \ldots, \delta_k \odot \gamma_k, \delta_0 \odot \gamma_0)$-computable.*

Proof.

(a) This follows from Theorem 6.2.
(b) This follows from Theorem 4.2.
(c) This follows from (a) and (b) by Lemma 6.5. □

7. Examples

The feasible real RAM [8], a machine model for real computation, allows approximate multi-valued branching.

$$\leq_k\colon \mathbb{R}\times\mathbb{R}\rightrightarrows\{\mathrm{tt},\mathrm{ff}\},\quad \leq_k(x,y)\begin{cases} =\mathrm{tt} & \text{if } x<y\\ \in\{\mathrm{tt},\mathrm{ff}\} & \text{if } y\leq x\leq y+2^{-k}\\ =\mathrm{tt} & \text{if } y+2^{-k}<x\,.\end{cases}$$

This is not allowed in generalized Turing machines but can be simulated by a multi-valued function followed by a single-valued test.

Theorems 6.2 and 6.6 allow to formulate algorithms and argue about them in a more abstract way which is closer to ordinary analysis and which usually is simpler and more transparent. In Example 6.4 we have used sequences of rational intervals as names of real numbers.

As another example consider $C^\infty(\mathbb{R})$ the set of all infinitely often differentiable real functions. There is a canonical representation β of $C(\mathbb{R})$, then $\gamma := [\beta]^\omega$ is a canonical representation of $(C(\mathbb{R}))^\omega$ [20, Definition 3.3.3]. Define a generalized representation $\delta :\subseteq (C(\mathbb{R}))^\omega \to C^\infty(\mathbb{R})$ as follows:

$$\delta(f_0,f_1,\ldots)=g \iff (\forall i)\, f_i = g^{(i)}$$

(a name of g is a list of all of its derivatives). This generalized representation may be useful in the study of distributions [22].

As another example we consider computing the sum $s := \sum_{j=0}^{\infty} a_j z^j$ of a complex power series. Let R be the radius of convergence and $s_n := \sum_{j=0}^{n-1} a_j z^j$ the partial sum of the first n terms. Let $r<R$, $r\in\mathbb{Q}$, and let $M\in\mathbb{Q}$ be a Cauchy constant for r, that is, $(\forall j)\,|a_j|\leq M\cdot r^{-j}$. Then for all $|z|<r$,

$$|s_n - s| \leq M\frac{(|z|/r)^n}{1-(|z|/r)}$$

We want to show that the operator $H:((a_j)_j,r,M,z)\to s$ is computable via the standard representations of the occurring sets [20]. In the following we say "computable" instead of "computable via the standard representations".

First, from the inputs $(a_j)_j$, r, M, z and k we compute some complex number $b_k\in\mathbb{C}$ such that $|b_k - s|\leq 2^{-k}$ as follows:
– compute $c := |z|/r$
– find some $q\in\mathbb{Q}$ such that $c<q<1$, (then $|s_n-s|\leq M\cdot q^n/(1-q)$)
– find some $n\in\mathbb{N}$ such that $M\cdot q^n/(1-q)<2^{-k}$, (then $|s_n-s|\leq 2^{-k}$)
– For $m=0,1,\ldots,n$ compute in turn z^m and s_m.
– Let $b_k := s_n$ be the result.

It is easy to find a generalized Turing machine **N** for this algorithm that uses the arithmetical operations on $\mathbb{N},\mathbb{Q},\mathbb{R}$ and $\mathbb{C}$ and the projection $((a_j)_j,m)\mapsto a_m$ all of which are computable [20]. Therefore, by Theorem 6.2, $f_N:((a_j)_j,r,M,z,k)\rightrightarrows b_k$ is computable. By [20, Theorem 35] the multi-function $S\circ f_N:((a_j)_j,r,M,z)\rightrightarrows(b_k)_{k\in\mathbb{N}}$ is computable, where

$$(b_k)_k\in S\circ f_N((a_j)_j,r,M,z) \iff (\forall k)\, b_k\in f_N((a_j)_j,r,M,z,k)\,.$$

Since $(b_k)_k$ is a sequence of complex numbers such that $|s-b_k|\leq 2^{-k}$ and the limit operator $\mathrm{Lim}:(b_k)_k\mapsto\lim_{k\to\infty}b_k$ is computable (cf. [20, Theorem 4.3.7], $H=\mathrm{Lim}\circ S\circ f_N$ is computable.

Although a multi-function has been used in the determination of q, the function H is single-valued. Notice that the only informal part in the above proof is the specification of the generalized Turing machine $\mathbf{N}$. But this method is customary and accepted in computability theory. Compare this proof with the proof of Theorem 4.3.11 in [20]. Via Lemma 4.3.6 it uses the closure of computable functions under primitive recursion (Theorem 3.1.7), which follows easily from Theorem 6.2 in this article.

In mathematical practice, often a function such as addition on $\mathbb{Q}$, is said to be computable "by Church's Thesis". In such a case, implicitly fixed "natural", "effective" or "canonical" representations by finite or infinite strings are presupposed such that the function is computable w.r.t. these representations. Usually there is no disagreement about the meaning of "natural", "effective" or "canonical". Often a canonical representation of a set X can be defined up to equivalence by requiring that the functions and (or) predicates of the natural structure for X must become computable, and requiring additionally that the representation is maximal or minimal w.r.t. reducibility $\leq$ when indicated.

Let us call sets on which computability can be defined by canonical representations "natural". Examples of natural sets Y are $\mathbb{N}$, $\mathbb{B} := \mathbb{N}^{\mathbb{N}}$ (Baire space), Γ^* and $\Gamma^{\mathbb{N}}$ (for finite Γ), $\mathbb{Q}$, $\mathbb{Q}^n$ and $\bigcup_n \mathbb{Q}^n$. Let us call a multi-representations $\delta : Y \rightrightarrows X$ natural if Y is natural. By Theorem 6.6, Theorem 7.1 can be generalized as follows.

Theorem 7.1 (informal generalization)**.** *Let* $\mathbf{P}$ *be a generalized Turing machine on sets with natural representations. Suppose that every function and test used in the machine has a realization that is computable by Church's Thesis. Then the function* f_P *computed by the machine is computable w.r.t. the natural representations.*

Brattka and Gherardi [7] use a reduction $\leq_W$ for comparing the non-computability of theorems in analysis. Formally, $\leq_W$ compares the non-computability of multi-functions on represented sets. We generalize this definition to multi-represented sets (Z_i, δ_i) $(i \in \{1, 2, 3, 4\})$: For $f : Z_1 \rightrightarrows Z_2$ and $g : Z_3 \rightrightarrows Z_4$. $f \leq_W g$, if there are computable functions G, H on Σ^ω such that $p \mapsto G(p, h \circ H(p))$ is a realization of f if h is a realization of g. The next theorem provides a method to prove $f \leq_W g$. We use the concept of *extension* for multi-functions from [21, Definition 7]. $f' : Z_1 \rightrightarrows Z_2$ extends $f : Z_1 \rightrightarrows Z_2$, if $\mathrm{dom}(f) \subseteq \mathrm{dom}(f')$ and $f'(x) \subseteq f(x)$ for all $x \in \mathrm{dom}(f)$.

For a generalized Turing machine $\mathbf{M}$ from Definition 3.1 let $\mathrm{graph}(\mathbf{M}) := (\mathcal{L}, S)$ where $(l, l') \in S$ ((l, l') is an edge), iff $\mathrm{Stm}(l)$ has the form $(\ldots, l')$, $(\ldots \text{then } l', \text{ else } l'')$ or $(\ldots \text{then } l'', \text{ else } l')$.

Theorem 7.2. *For multi-functions* f, g *on multi-represented sets such that* g *is not computable,* $f \leq_W g$ *if there is a generalized Turing machine* $\mathbf{N}$ *on represented sets such that*

(1) *every test in* $\mathbf{N}$ *is computable,*
(2) *for every statement of the form* $(i := c(i_1, \ldots, i_n), l')$*, either* c *is computable or it is of the form* $(i := g(i_1), l')$*.*
(3) *every path in* $\mathrm{graph}(\mathbf{N})$ *starting at* l_0 *visits at most once a label* l *such that* $\mathrm{Stm}(l)$ *applies the function* g*.*
(4) f_N*, the function computed by* $\mathbf{N}$*, extends* f*.*

(where "computable" means computable w.r.t the given multi-representations.)

Condition (3) for the GTM can be enforced easily syntactically. The theorem generalizes one direction of [11, Lemma 4.5].

Proof. Let $h :\subseteq \Sigma^\omega \to \Sigma^\omega$ be a realization of g. There is a generalized Turing machine $\mathbf{M}$ on Σ^ω that realizes $\mathbf{N}$ (Definition 4.1) such that in $\mathbf{M}$ every test is computable, every function is computable or equal to h and Condition (3) is true for $\mathbf{M}$ and h. By Theorem 4.2, f_M realizes f_N and hence f_M realizes f.

For computing the functions G and H, from the machine $\mathbf{M}$ we construct machines $\mathbf{M}_G$ and $\mathbf{M}_H$. Let $\mathbf{M} = (\mathcal{L}, l_0, l_f, \Gamma, b, 1, L, (X_i)_{0\le i\le L}, \mathrm{Stm})$ where $X_i = \Sigma^\omega$ for all i.

Define $\mathbf{M}_H := (\mathcal{L}, l_0, l_f, \Gamma, b, 1, L, (X_i)_{0\le i\le L}, \mathrm{Stm}_H)$ such that for all l, l', i, i_1,

$$\mathrm{Stm}_H(l) := \begin{cases} (0 := \mathrm{id}_{\Sigma^\omega}(i_1), l_f) & \text{if } \mathrm{Stm}(l) = (i := h(i_1), l'), \\ \mathrm{Stm}(l) & \text{otherwise}. \end{cases}$$

Then for input $p \in \mathrm{dom}(f_M)$, the machine $\mathbf{M}_H$ computes the argument for h if a statement with h is visited during the computation and computes the value $f_M(p)$ otherwise.

Define $\mathbf{M}_G := (\mathcal{L}, l_0, l_f, \Gamma, b, 1, L+1, (X_i)_{0\le i\le L+1}, \mathrm{Stm}_G)$ such that $X_{L+1} := \Sigma^\omega$ and for all l, l', i, i_1,

$$\mathrm{Stm}_G(l) := \begin{cases} (i = \mathrm{id}_{\Sigma^\omega}(i_{L+1}), l') & \text{if } \mathrm{Stm}(l) = (i := h(i_1), l'), \\ \mathrm{Stm}(l) & \text{otherwise}. \end{cases}$$

Then the machine $\mathbf{M}_G$ works in the same way as the machine $\mathbf{M}$ except for statements $(i := h(i_1), l')$ of $\mathbf{M}$ where instead of applying h, $\mathbf{M}_G$ copies the value q scanned by the head on Tape $L+1$ to the cell scanned by the head on Tape i. For avoiding renaming of tapes we may assume w.l.o.g. that the machine $\mathbf{M}_G$ has the two input tapes 1 and $L+1$. Obviously for all $p \in \mathrm{dom}(f_M)$, $f_M(p) = f_{M_G}(p, h \circ f_{M_H}(p))$. Define $H := f_{M_H}$ and $G := f_{M_G}$. □

Theorem 7.2 holds accordingly for continuous reducibility instead of computable reducibility.

8. Conclusion

We have introduced the Generalized Turing machine as a simple general model of computation. This model is not intended for implementation on computers but as a mathematical tool for proving computability in Analysis. Although the three main theorems 5.7, 6.2 and 6.6 seem to be obvious and hence have already been applied informally without proofs, this article shows that even for our very meagre model of computation the proofs require some care.
